

EP.108 1X EQUIPS NEO WITH HUMAN-LEVEL DEXTEROUS HANDS

Chinese robotics startups eyeing IPOs, South Korean humanoid player raised new capital & much more...

LUKAS ZIEGLER

JUL 15, 2026

What's inside (version for the busiest people)

1X equips NEO with human-level dexterous hands

- 25 actuated DOF, 5-to-15:1 gear ratios, tendon-driven enabling force transparency and tactile sensing
- What backdrivable joints revealing grip pressure, contact location, shear demonstrates: hands simultaneously motors and sensors

LimX Dynamics prepares IPO at \$2.21B valuation

- Chinese humanoid startups rushing public listings as investment hits \$6.95B in Q2 alone (6x YoY)
- Why "0 to 1" innovation crossed, next barrier is product-market fit not technology → 100+ Chinese humanoid companies competing, Unitree fast-tracked Shanghai listing, 50K humanoid shipments forecast

Holiday Robotics raises \$105M Series A, largest Korean humanoid round

- Friday robot built around 64 DOF (40 in hands) with tactile sensing, force-aware control, wheel-based mobility
- What Vision-Language-Skill (VLS) stack reveals: vision/language define goals, reusable skills execute with full deployment infrastructure in-house

NVIDIA and Hugging Face integrate Isaac GR00T 1.7 into LeRobot

→ Open reasoning VLA model + Isaac Teleop framework for human demonstrations now in open source library

→ What 350K trajectories, 57M grasps, 15M dataset downloads demonstrate about democratizing robot development

Human-level hands? 1X just gave humanoid robot NEO something close! 🤖

1X has released the hands for its NEO humanoid robot, showcasing unprecedented speed and precision. The headline spec: 25 degrees of freedom, all of them actuated, and tendon-driven motion, resulting in what 1X calls near human-level dexterity, strength, and reliability. The hands have enough strength to lift a 20-pound kettlebell yet enough delicacy to pick grapes off their stems, install a light bulb, and pick up a screw off the floor.

Most robot hands are essentially “write-only”, you command the hand to move to a position, it goes there, and no data comes back. It doesn’t feel anything the way a human feels things, thanks to aggressive gearing (often 100-to-1 or 200-to-1) that swallows any contact force feedback before it reaches the motor. Neo’s hand runs at dramatically lower gear ratios, roughly 5-to-1 to 15-to-1, using tendons to pull the fingers. The result is that every single joint is simultaneously a motor and a sensor—push on a finger and it gives (it’s backdrivable), and it reports exactly how hard you pushed. 1X calls this “force transparency”: force flows out, information flows back, and the robot knows what’s happening at its fingertips.

There’s also a skin layer doing real work: high-resolution tactile sensing across the fingertips that measures pressure, contact location, and shear, the sideways force that tells the hand something is about to slip.

So when an object starts sliding out of its grip, Neo can theoretically feel it and re-grip in real time, just like humans.

Uniquely, these hands are washable, IP68 sealed, just like a phone, so Neo can immerse them in water without any problems. That means Neo can fry an egg or chop vegetables and then clean up after itself, rather than spreading mess around the house. 1X says the hands have been through millions of test cycles, with wrist joints proven past two million cycles under load.

As 1X points out, while legs are for getting a robot somewhere and the body houses the battery and compute, the hands are what do the actual work—folding clothes, putting away laundry, cooking, whatever the chore is. Notably, Neo will ship with more hardware capability than the AI currently knows how to use, meaning over-the-air updates should make each Neo progressively smarter over time.

Chinese humanoid startups are rushing to launch IPOs!

Humanoid startup LimX Dynamics is getting ready to go public, just over four years after it was founded during the pandemic. “Listing is a must,” said founder Will Zhang, emphasizing the importance of timing, ahead of the company’s announcement that it had raised \$200 million in a pre-IPO round valuing the startup at 15 billion yuan (\$2.21 billion). Several overseas investors participated, including UAE-based Stone Venture, Italy-based GGG, and Germany-based Redstone VC. The startup said it is already preparing for its IPO, likely in Hong Kong, and is in a confidential phase of review.

Zhang compared the situation to Chinese electric car startups Nio, Xpeng, and Li Auto, which successively listed in the U.S. from 2018 to 2020. “Once the technology is mature, if [the company] doesn’t list, then like WM Motor, it may disappear,” he said. The urgency comes as China now has well over 100 humanoid companies, which fall under the national push for “embodied AI.” Reflecting a rapid surge in interest, investment in the sector hit 47.09 billion yuan (\$6.95 billion) in the second quarter, more than double that of the first quarter, and up over six times versus the same period last year, according to industry data provider Xiniu.

China has fast-tracked approval for humanoid company Unitree to list in Shanghai, while Hong Kong processes applications from more than 500 companies across sectors. “With more industrial and collaborative robot companies potentially coming to IPO, competitive pressure is likely to persist,” Morgan Stanley said in a report, noting sector players DeepRobot and Leju that are looking to list soon. The investment firm forecasts 18% growth in China’s industrial robots market this year, and shipment of 50,000 humanoids.

LimX aims to create fully autonomous commercial service robots. The company said it will kick off a multi-year plan to ship thousands of humanoids to the Middle East, and is delivering its entertainment-focused Luna humanoid to customers in South Korea. To Zhang, the technology behind humanoid robots has already crossed the “0 to 1” line of innovating from scratch—the next barrier to entry lies in making a good product that meets users’ needs. Other backers in the latest round include Chinese precision parts company Lens Technology, IDG Capital, WestSummit Capital, Nio Capital, and Hefei Binhu Industry Development Group.

Holiday Robotics raises \$105M in Series A funding!

South Korea's Holiday Robotics has raised \$105 million in Series A funding to develop dexterous humanoid robots for industrial work. South Korean business newspaper Maeil Business reported that the round is the largest Series A investment for a South Korean startup and the largest single funding round for a South Korean humanoid robot company. Existing investors Stone Bridge Ventures, Atnum Investments, Intervest, and Spring Camp participated, alongside new backers including IMM Investment, SL Investment, KB Investment, Bon Angels Venture Partners, and Goodwater Capital. Financial institutions including Korea Development Bank and Industrial Bank of Korea also participated.

Founded in 2024, the company will use the capital to grow its research and engineering teams, strengthen manufacturing readiness, and continue developing Friday, its humanoid robot. The company's approach starts with hands. Holiday said humanoid robots create industrial value through grasping, placing, adjusting, sensing contact, and repeating precise movements, tasks difficult to automate because they involve friction, weight, alignment, and surface variation. Friday has 64 degrees of freedom, with 40 dedicated to its hands. The robot is built around high-dexterity hands, tactile sensing across the hand, and force-aware control that allows it to feel contact and adapt to it. It uses a wheel-based mobile base to move through factories, a dexterous upper body for manipulation, and hot-swappable batteries to support full-shift operation. Safety is built into the hardware, with lightweight hands, fully backdrivable hand and arm joints, and 360-degree perception using multiple cameras and LiDARs.

Holiday is also developing its software and deployment stack in-house, built around what the company calls Vision-Language-Skill (VLS). In that approach, vision and language help define what a robot should do, while reusable skills define how the robot performs the task. The full-stack system includes Friday, Holiday Sim (a simulation environment), Holiday Lab (a system for turning demonstrations and failures into reusable skills), and OASys (a deployment system).

Robotics Maps - The Bay Area

This is the capital of robotics! 

Silicon Valley is home to so many physical AI companies that you could spend a month visiting them and still not see even 10% of them (trust me, I tried).

So, the Bay Area is the world's leading ecosystem for robotics startups, bringing together top AI talent, top universities, experienced founders, and unmatched access to capital.

The region is anchored by Stanford University and University of California, Berkeley, two of the world's top universities for AI and robotics. They produce a constant stream of researchers, founders, and breakthrough technologies.

NVIDIA and Hugging Face bring new models and frameworks for the open robotics community! 🔒

NVIDIA and Hugging Face are collaborating to bring the NVIDIA Isaac GR00T 1.7 open reasoning vision-language-action (VLA) model for humanoid robots and the NVIDIA Isaac Teleop framework to LeRobot—Hugging Face’s open source library for robotics, with NVIDIA Cosmos 3, a frontier model for physical AI, planned soon. Together, these integrations give developers a more accessible and standardized path for end-to-end robot development while driving innovation and collaboration across the open robotics community.

The integrations include NVIDIA Isaac Teleop (an open source framework for robot data collection that captures high-quality human demonstrations), NVIDIA Isaac GR00T 1.7 (the first open and commercially viable robot foundation model), and the upcoming NVIDIA Cosmos 3 (a frontier world foundation model that will help developers generate and augment robotics data and simulate scenarios when real-world data is limited).

These integrations build on a broader set of NVIDIA resources already connected to LeRobot. That includes the largest open source physical AI dataset—downloaded more than 15 million times—which features more than 350,000 real and simulated trajectories and 57 million grasps. It also includes NVIDIA Isaac Sim- and Isaac Lab-based simulation frameworks to help developers set up environments, generate robot data, and validate behaviors before moving to physical robots, plus NVIDIA Isaac Lab-Arena in the LeRobot Environment Hub for prototyping complex simulation environments.
